

# DUAL ROUTER SETUP

Switch seamlessly between local and VPN network  
on any device, anytime!

## How It Works

If you have a wireless network in your home or office then you most likely already have a router in place. However there are many reasons why this router alone will not be enough to take care of all your networking needs. Internet Service Providers (ISPs) will often provide a modem/router combo device that can be locked down with limited features and limited wireless range, or perhaps you purchased a router several years ago that still works but is lacking the features and functionality you desire.

It is possible to overcome these problems by simply adding a FlashRouter into your network. Use any open port on your main router or modem/router to connect to the FlashRouter Internet

port, thereby creating a separate and unique wireless network. By connecting a FlashRouter into your existing setup, you can unlock enterprise features like VPN connectivity, bandwidth monitoring, access restrictions, and much more.

Best of all though, you do not have to change a single setting on your existing router; you will still have the same old network up and running with a connection through your local ISP. With the FlashRouters Dual Router Setup you can have a VPN network with advanced configuration options up and running at the exact same time. For VPN users this means you can pick and choose on any wireless device whether you want an anonymous VPN connection in the virtual geographic location of your choice or a local ISP connection through your actual location.
